

# Simplification of the Keiper/Li approach to the Riemann Hypothesis (RH)

**André Voros**

CEA-Institut de Physique Théorique de Saclay

8th DynQua Meeting, Grenoble, Feb. 4, 2016

Based on preprint IPhT15/106 (June 2015), HAL cea-01166324

NOT ABOUT - “proofs” of RH

- importance of RH for number theory

ONLY ABOUT

criteria (rewordings, equivalent statements, tests) for RH

## The Riemann zeta function $\zeta(x)$

$$\begin{aligned} \zeta(x) &\stackrel{\text{def}}{=} \sum_{k=1}^{\infty} k^{-x} && (\text{Re } x > 1) \\ &\equiv \prod_{\{p\}} (1 - p^{-x})^{-1} && (\text{Euler product: i.e., } \log \zeta \text{ encodes the primes}) \\ &\equiv \frac{1}{\Gamma(x)} \int_0^{\infty} \frac{1}{e^u - 1} u^{x-1} du && (\text{Mellin transformation}) \end{aligned}$$

which extends  $\zeta$  to  $\mathbb{C}$  with the only singularity  $\zeta(x) = \frac{1}{x-1} + \dots$ , and

$$\zeta(-n) = (-1)^n B_{n+1} / (n+1) \quad \text{for } n = 0, 1, 2, \dots$$

(Poisson's summation formula  $\Rightarrow$ ) **Riemann's Functional Equation:**

$$\boxed{\xi(x) \equiv \xi(1-x)} \quad \text{for } 2\xi(x) \stackrel{\text{def}}{=} x(x-1)\pi^{-x/2}\Gamma(x/2)\zeta(x) \text{ (completed zeta function).}$$

$\xi$  is an entire function, with these **symmetries** besides  $x \leftrightarrow (1-x) : \text{Im} \leftrightarrow -\text{Im}$  (reality), hence also symmetry / **critical line**  $\{\text{Re } x = \frac{1}{2}\}$ .

$\log 2\xi(1/2+t)$

$\log |2\xi(1/2+iT)|$

**Riemann zeros** = zeros of  $\xi(x)$  (denoted  $\{\rho\}$ ), the lowest ones being

$$\rho = \frac{1}{2} \pm iT, \quad T \approx 14.1347251, 21.0220396, 25.0108576, 30.4248761, 32.9350616, \dots$$

## The Riemann zeros - proven facts

- Countably many zeros, all in the open *critical strip*  $\{0 < \operatorname{Re} x < 1\}$ .

- Riemann–von Mangoldt theorem* for the zeros' counting function  $N(T)$  :

$$N(T) = \frac{T}{2\pi} \left( \log \frac{T}{2\pi} - 1 \right) + \delta N(T), \quad \delta N(T) = O(\log T) \text{ as } T \rightarrow +\infty.$$

- Hadamard product formula*:  $2\xi(x) \equiv \prod_{\langle \rho, 1-\rho \rangle} (1 - x/\rho).$

## The Riemann Hypothesis (RH) (1859)

All the zeros  $\rho$  of  $\xi(x)$  lie on the axis  $\{\operatorname{Re} x = \frac{1}{2}\}$  (the **critical line**)

Numerically verified up to the  $10^{13}$ -th zero or the height  $T_0 \approx 2.4 \cdot 10^{12}$  (Gourdon 2004).

Significance for number theory: the Prime Number Theorem for the primes' counting function  $\pi(k)$  states

$$\pi(k) \sim \operatorname{Li}(k) \stackrel{\text{def}}{=} \int_2^k \frac{dv}{\log v} \quad \left( \approx \frac{k}{\log k} \right) \quad \text{for } k \rightarrow \infty.$$

Then, **RH optimizes the error term**  $\varepsilon(k) = \pi(k) - \operatorname{Li}(k)$  :

$$\beta_0 \stackrel{\text{def}}{=} \sup_{\rho} \{\operatorname{Re} \rho\} \equiv \inf \{ \beta \in \mathbb{R} \mid \varepsilon(k) = O(k^\beta) \},$$

and RH ( $\iff \beta_0 = \frac{1}{2}$ ) more precisely amounts to  $\varepsilon(k) = O(k^{1/2} \log k)$  : the least possible fluctuation for the primes' distribution function  $\pi(k)$  around its mean  $\operatorname{Li}(k)$ .

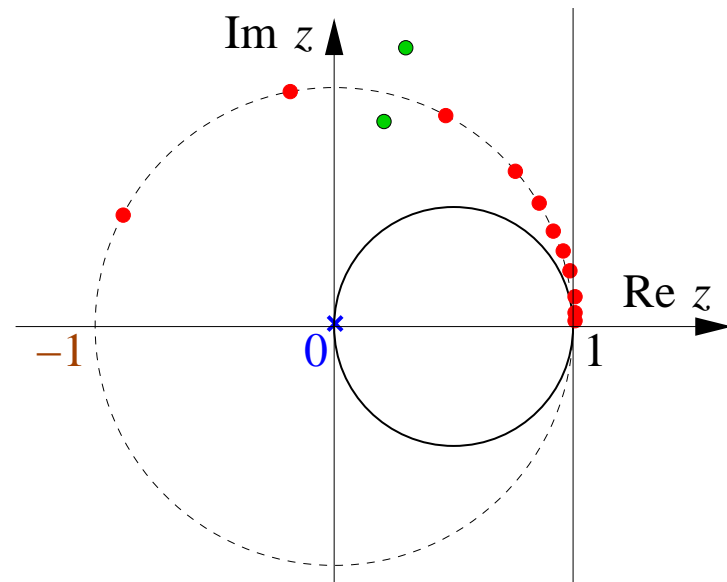

But currently:      RH true or not?       $\beta_0 < 1$  or  $\beta_0 = 1$ ?

## The Keiper/Li sequence as a testing tool for RH

Defined by the (real) generating function (Keiper 1992, X.-J. Li 1997)

$$\sum_{n=1}^{\infty} \lambda_n z^{n-1} \equiv F(x(z)) \stackrel{\text{def}}{=} \frac{d}{dz} \log 2\xi\left(x = \frac{1}{1-z}\right) \iff \lambda_n = \sum_{\langle \rho, 1-\rho \rangle} [1 - (1-1/\rho)^n].$$

$$\lambda_1 = 1 - \frac{1}{2} \log 4\pi + \frac{1}{2} \gamma \approx 0.0230957, \quad \lambda_2 \approx 0.0923457, \quad \lambda_3 \approx 0.207639, \dots$$

$$\text{RH} \iff \text{all } z_\rho = 1 - 1/\rho \text{ on } \{|z| = 1\}.$$

$$x = \frac{1}{1-z} \iff z = 1 - 1/x$$

$$x = \frac{1}{2} + iT \iff z = e^{i\theta}, \quad T \equiv \frac{1}{2} \cot \frac{1}{2}\theta.$$

$$\rho = \frac{1}{2} \pm iT\rho \iff z_\rho = e^{\pm i\theta_\rho}; \quad \text{Re } \rho = \frac{1}{2} \iff \theta_\rho \text{ real.}$$

$$\lambda_n = \sum_{\langle \rho, 1-\rho \rangle} [1 - (1 - 1/\rho)^n] \equiv \sum_{\langle \rho, 1-\rho \rangle} (1 - z_\rho^n) \equiv \sum_{\langle \rho, 1-\rho \rangle} (1 - \cos n\theta_\rho).$$

## If RH is true...

$$\lambda_n = \sum_{\langle \rho, 1-\rho \rangle} (1 - \cos n\theta_\rho) \quad \text{with all } \theta_\rho \text{ real}$$

implies, for the  $\lambda_n$ ,

- positivity:

$$\boxed{\lambda_n > 0 \quad \text{for all } n} \quad (\text{Keiper 1992})$$

- large-order behavior through the integral formula (Oesterlé 2000)

$$\lambda_n = 2 \int_0^\infty (1 - \cos n\theta) dN(T) \implies \frac{\lambda_n}{n} = 2 \int_0^\pi \sin n\theta N\left(\frac{1}{2} \cot \frac{1}{2}\theta\right) d\theta$$

and using  $N(T) = \frac{T}{2\pi} \left( \log \frac{T}{2\pi} - 1 \right) + \delta N(T)$ ,  $\delta N(T) = O(\log T)_{T \rightarrow +\infty}$ ;

- $\int_0^\pi \sin n\theta \delta N\left(\frac{1}{2} \cot \frac{1}{2}\theta\right) d\theta \rightarrow 0$  (Riemann–Lebesgue lemma)
- $\frac{\lambda_n}{n} \sim 2 \int_0^\infty \sin \Theta \frac{n}{2\pi\Theta} \left[ \log \frac{n}{2\pi\Theta} - 1 \right] \frac{d\Theta}{n}$  using  $\Theta \stackrel{\text{def}}{=} n\theta$ ,  $T \sim n/\Theta$ .
- $\int_0^\infty \sin \Theta \frac{d\Theta}{\Theta} = \frac{1}{2}\pi$ ,  $\int_0^\infty \sin \Theta \log \Theta \frac{d\Theta}{\Theta} = -\frac{1}{2}\pi\gamma \implies$

$$\boxed{\frac{\lambda_n}{n} \sim \frac{1}{2} \log n + \frac{1}{2}(\gamma - \log 2\pi - 1)}$$

## Asymptotic sensitivity to RH

Large-order behavior of  $\lambda_n$  : using Darboux's method for  $F(x(z)) \stackrel{\text{def}}{=} \frac{d}{dz} \log 2\xi\left(x = \frac{1}{1-z}\right)$ , a meromorphic function having simple poles at all images  $z_\rho$  of Riemann zeros,

$$\lambda_n = \frac{1}{2\pi i} \oint_C z^{-n} F(x(z)) dz = - \sum_{\{|z_\rho| < 1\}} z_\rho^{-n} + o(r^{-n})_{n \rightarrow \infty} \text{ for all } r < 1.$$

## Two concrete criteria for RH

- Li's criterion (X.-J. Li 1997): **RH true**  $\iff \lambda_n > 0$  for all  $n$
- Asymptotic alternative (AV 2004, by saddle-point method on  $\lambda_n$  as an integral)

$$\lambda_n \sim \begin{cases} - \sum_{\{|z_\rho| < 1\}} z_\rho^{-n} + o(r^{-n})_{n \rightarrow \infty} \text{ for all } r < 1 & \text{if RH false} \\ & \text{(exponentially growing oscillations of both signs)} \\ \frac{1}{2}n \log n + \frac{1}{2}n(\gamma - \log 2\pi - 1) + O(n^{1/2} \log n) & \text{if RH true} \\ & \text{(tempered growth to } +\infty \text{) (Lagarias 2007)} \end{cases}$$

Practical aspects:

- RH verified up to a height  $T_0 \implies \lambda_n > 0$  as long as  $n < T_0^2$
- a Riemann zero violating RH,  $\rho = \frac{1}{2} + t \pm iT$  with  $0 < t (< \frac{1}{2})$  (hence  $T > T_0$ ), will practically be undetectable through  $\lambda_n$  unless

$$n \gtrsim T^2/t > 2T^2 \quad (\gtrsim 10^{25} \text{ currently : } T_0 \approx 2.4 \cdot 10^{12}).$$

## Computing the $\lambda_n$

$$\lambda_n = 1 - \frac{1}{2}(\log 4\pi + \gamma)n + \sum_{j=2}^n (-1)^j \binom{n}{j} (1 - 2^{-j})\zeta(j) - \sum_{j=1}^n \binom{n}{j} \eta_{j-1}$$

(Bombieri–Lagarias 1999)

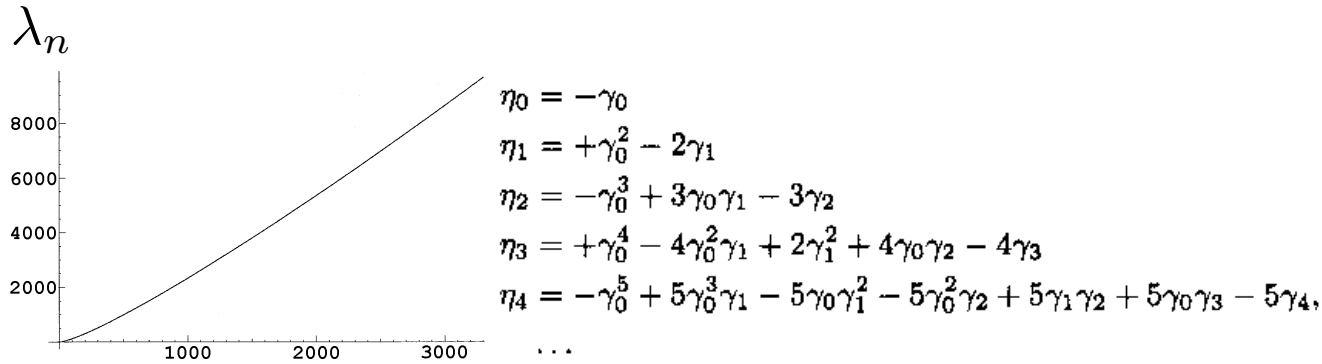

$$\log[(x-1)\zeta(x)] \equiv - \sum_{n=0}^{\infty} \frac{\eta_n}{n+1} (x-1)^{n+1}$$

$$\text{vs } (x-1)\zeta(x) \equiv \sum_{n=0}^{\infty} \gamma_n (x-1)^{n+1} \quad (\text{Stieltjes constants: } \gamma_0 \equiv \gamma)$$

In terms of the *von Mangoldt function*  $\Lambda(k) \stackrel{\text{def}}{=} \begin{cases} \log p & \text{if } k = p^r, p \text{ prime} \\ 0 & \text{otherwise} \end{cases}$ :

$$\eta_n = \frac{(-1)^n}{n!} \lim_{K \rightarrow \infty} \left\{ \sum_{k=2}^K \Lambda(k) \frac{(\log k)^n}{k} - \frac{(\log K)^{n+1}}{n+1} \right\} \quad (\eta_0 \equiv -\gamma).$$

## Numerical computations (also: Coffey 2005)

Maślanka 2004

Keiper 1992

$$\lambda_n - \left[ n \log n + \frac{1}{2} n (\gamma - \log 2\pi - 1) \right]$$

## Deformations of the $\lambda_n$ : allowed?

$$\lambda_n = \frac{1}{(n-1)!} [x^{n-1} \log 2\xi(x)]_{x=1}^{(n)} \iff \sum_{n=1}^{\infty} \lambda_n z^{n-1} \equiv \frac{d}{dz} \log 2\xi\left(\frac{1}{1-z}\right)$$

## Deformations of the $\lambda_n$ : allowed!

$$\lambda_n = \frac{1}{(n-1)!} [x^{n-1} \log 2\xi(x)]_{x=1}^{(n)} \iff \sum_{n=1}^{\infty} \lambda_n z^{n-1} \equiv \frac{d}{dz} \log 2\xi\left(\frac{1}{1-z}\right)$$

(Sekatskii 2014)

$$\lambda_n^{(b)} = \frac{2b+1}{(n-1)!} [(x+b)^{n-1} \log 2\xi(x)]_{x=1+b}^{(n)} \iff \sum_{n=1}^{\infty} \lambda_n^{(b)} z^{n-1} \equiv \frac{d}{dz} \log 2\xi\left(\frac{bz+1+b}{1-z}\right)$$

## Numerical observations

$$\frac{1}{2}(\log 2\xi)''\left(\frac{1}{2}\right) = 0.0231050\dots$$

$$-4 \log 2\xi\left(\frac{1}{2}\right) = 0.0231003\dots$$

$$(\log 2\xi)'(1) \equiv \lambda_1 = 0.0230957089661210\dots$$

## We propose broader deformations

$$\lambda_n = \frac{1}{(n-1)!} [x^{n-1} \log 2\xi(x)]^{(n)} \Big|_{x=1} \iff \sum_{n=1}^{\infty} \lambda_n z^{n-1} \equiv \overbrace{\frac{d}{dz} \log 2\xi(x(z))}^F \underbrace{\frac{1}{1-z}}$$

$$\lambda_n = \frac{1}{2\pi i} \oint_C \frac{dz}{z^n} F(x(z)), \iff$$

Denominator:

$z^n$

## We propose broader deformations

$$\lambda_n = \frac{1}{(n-1)!} [x^{n-1} \log 2\xi(x)]^{(n)} \Big|_{x=1} \iff \sum_{n=1}^{\infty} \lambda_n z^{n-1} \equiv \overbrace{\frac{d}{dz} \log 2\xi(x(z))}^F \underbrace{\frac{1}{1-z}}$$

$$\lambda_n = \frac{1}{2\pi i} \oint_C \frac{dz}{z^n} F(x(z)), \iff$$

Denominator:  $z^n \mapsto$  New denominator  $(z - z_1) \cdots (z - z_n)$

## Asymptotic alternative (AV 2015)

$$\Lambda_n \sim \begin{cases} \sum_{\{\operatorname{Re} \rho > 1/2\}} e^{i\phi(\rho)} \frac{(-1)^n (2n)^{\operatorname{Re} \rho - 1/2}}{|\operatorname{Im} \rho|^{\operatorname{Re} \rho + 3/2} \log n} & \text{if RH false} \\ \log n + \frac{1}{2}n(\gamma - \log \pi - 1) + o(1) & \text{if RH true} \end{cases}$$

(power-like oscillations of both signs)

(tempered growth to  $+\infty$ )

$$\lambda_n = \frac{1}{2\pi i} \oint_C \frac{F}{z^n} dz \sim - \sum_{\{|z_\rho| < 1\}} z_\rho^{-n}; \quad \Lambda_n \sim \frac{1}{2\pi i} \oint_{C_n} G n^{x-1/2} dx \sim \sum_{\{\operatorname{Re} \rho > 1/2\}} e^{i\phi(\rho)} \frac{(-1)^n (2n)^t}{|T|^{t+2} \log n}$$

## Numerical computation of the $\Lambda_n$

$\Lambda_n$  computed up to  $n = 4000$ , on a logarithmic  $n$ -scale; straight line: the asymptotic form

$$\bar{\Lambda}_n = \log n + \frac{1}{2}(\gamma - \log \pi - 1) \approx \log n - 0.78375711.$$

$$\Lambda_1 = \frac{3}{2} \log \frac{\pi}{3} \approx 0.0691764, \quad \Lambda_2 \approx 0.2274543, \quad \Lambda_3 \approx 0.4567141$$

## Adjustable precision $p(m) \approx \log_{10} |s_{nm}| + D$

```
In[1]:= p:=Floor[0.76555 n] + 16
```

$$\log_{10} |s_{nm}| \sim \left[ -2 \frac{m}{n} \log_{10} \frac{m}{n} + \left(1 + \frac{m}{n}\right) \log_{10} \left(1 + \frac{m}{n}\right) - \left(1 - \frac{m}{n}\right) \log_{10} \left(1 - \frac{m}{n}\right) \right] n$$

The remainder sequence  $\delta\Lambda_n = \Lambda_n - \bar{\Lambda}_n$  (in gray), and a rectified form  $(-1)^n \delta\Lambda_n$  (black dots) to cancel the period-2 oscillations.

Averaged and rescaled remainder sequence  $n \overline{\delta\Lambda}_n \stackrel{\text{def}}{=} \frac{1}{2}n(\delta\Lambda_n + \delta\Lambda_{n-1})$ .
